Noise is your friend

P. Cvitanović, J.M. Heninger and D. Lippolis

November 15, 2019

Outline

1 **what this is about**

- a geophysical prelude

-

3 **dynamicist's view of noise**

- idea: evolve densities, not noisy trajectories
-

should you listen to the weatherman?

Brian Farrell

"Traditionally, a statistical quantity is obtained from an ensemble average of sample realizations of the turbulence"

instead:

"statistical state dynamics (SSD) takes probability density function (pdf) as a state variable. Its dynamics has one and only one fixed point ($\cdots$polar jet$\cdots$), and only SSD equations reveal it" (huh?)

"the Fokker-Planck equation is intractable for representing complex system dynamics" (that is what we'll use in this talk :)

- B F Farrell and P J Ioannou, *Statistical State Dynamics: a new perspective on turbulence in shear flows*; arXiv.org:1412.8290

statistical state dynamics

Brian Farrell

- take 2-layer baroclinic turbulence model
- truncate SSD to the first two cumulants: mean flow, perturbation state covariance C
- closure (drop higher cumulants) by stochastic forcing Q
- Lyapunov equation

$$\frac{dC}{dt} = \mathrm{A\,C} + \mathrm{C\,A}^{\dagger} + \epsilon \mathrm{Q}\,, \quad \mathrm{A} = \text{linearized flow}$$

makes entry into climate science (at a baby level, *enfin*!) as the attractive fixed point of SSD

fixed point SSD

works on Jupiter

see the breakfast talk min 37:00 to 44:00

beyond fixed points : quasi-bilinear oscillation

works on Earth

the same video, continued :

- every 13.5 months equatorial winds reverese direction
- SSD explanation: Hopf bifurcation to an attractive limit cycle

noise rules the state space

> Science originates from curiosity and bad eyesight.
>
> — Bernard de Fontenelle,
> *Entretiens sur la Pluralité des Mondes Habités*

in practice

every physical problem is coarse partitioned by noise

noise rules the state space

> Science originates from curiosity and bad eyesight.
>
> — Bernard de Fontenelle,
> *Entretiens sur la Pluralité des Mondes Habités*

in practice

every physical problem is coarse partitioned by noise

- any physical system experiences (some kind of) noise
- any numerical computation is ‘noisy’
- any prediction only needs a desired finite accuracy

dynamics + noise: unique coarse-grained partition

reasonable to assume that the noise

is uniform,
leading to a uniform grid partition of the state space

in dynamics, this is wrong!

noise always has memory

dynamics + noise: unique coarse-grained partition

noise memory

accumulated noise along dynamical trajectories
always coarsens the $\mathrm{state\ space}$ nonuniformly

dynamical system

state space

a manifold $\mathcal{M} \in \mathbb{R}^d$: d numbers determine the state of the system

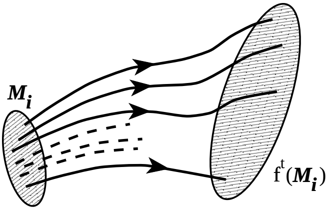
representative point

$x(t) \in \mathcal{M}$
a state of physical system at instant in time

dynamics

map $f^t(x_0)$ = representative point time t later

evolution in time



f^t maps a region $\mathcal{M}_i$ of the state space into the region $f^t(\mathcal{M}_i)$

how big is the neighborhood blurred by the accumulated noise?

the (well known) **key formula** that we now derive:

$$Q_{n+1} = M_n Q_n M_n^T + \Delta_n$$

density covariance matrix at time n: Q_n
noise covariance matrix: Δ_n
Jacobian matrix of linearized flow: M_n

Lyapunov equation, doctoral dissertation 1892
Ornstein-Uhlenbeck 1930
Kalman filter ‘prediction’ 1960

continuous time stochastic dynamical system $(\mathcal{M}, v, \sigma)$

$$dx = v(x)\,dt + \sigma(x)\,d\hat{\xi}(t)$$

x a point in state space $\mathcal{M}$
$v(x)$ the deterministic velocity field or 'drift'
$d\hat{\xi}(t)$ the standard Brownian noise, uncorrelated in time

$$\langle d\hat{\xi}_i(t')\,d\hat{\xi}_j^\top(t)\rangle = \delta_{ij}\,\delta(t-t')dt$$

the noise

anisotropic, state dependent and multiplicative
strength given by
diffusion matrix $\sigma(x)$, or
noise covariance matrix is $\Delta(x) = \sigma\,\sigma^\top$

strategy

assume the noise is weak
(i.e., deterministic dynamics dominates for short times)

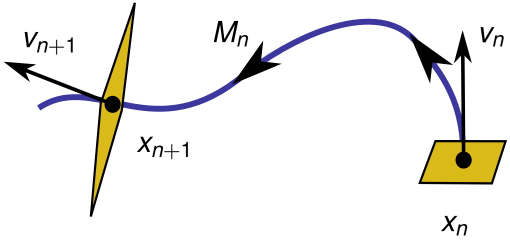
focus on behavior in the vicinity of an equilibrium point
(the argument is valid for any orbit of the system)

1. consider the action of the deterministic dynamics

2. consider the action of the noise
   as if the dynamics were absent

3. the noise and deterministic dynamics combined describe
   the noisy flow

linearized deterministic flow



$$x_{n+1} + z_{n+1} = f(x_n) + M_n\, z_n\,, \quad M_{ij} = \partial f_i / \partial x_j$$

in one time step a linearized neighborhood of x_n is

(1) advected by the flow

(2) transported by the Jacobian matrix M_n into a neighborhood given by the M eigenvalues and eigenvectors

covariance advection

let the initial density of deviations z from the deterministic center be a Gaussian whose covariance matrix is

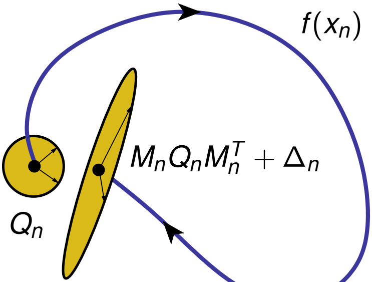
$$Q_{jk} = \langle z_j z_k^T \rangle$$

a step later the Gaussian is advected to

$$\begin{aligned} \langle z_j z_k^T \rangle &\rightarrow \langle (M\,z)_j\,(M\,z)_k^T \rangle \\ Q &\rightarrow M\,Q\,M^T \end{aligned}$$

next: add noise

roll your own cigar



in one time step
a Gaussian density distribution with covariance matrix Q_n is

(1) advected by the flow

(2) smeared with additive noise

into a Gaussian 'cigar' whose widths and orientation are given by the singular values and vectors of Q_{n+1}

covariance evolution

$$Q_{n+1} = M_n Q_n M_n^T + \Delta_n$$

(1) advect deterministically
local density covariance matrix $Q \to MQM^T$

(2) add noise covariance matrix Δ

covariances add up as sums of squares

cumulative noise along a trajectory

iterate $Q_{n+1} = M_n Q_n M_n^T + \Delta_n$ along a trajectory

if M is contracting, $|\Lambda_j| < 1$,

the memory of the covariance Q_0 of the starting density is lost, with iteration leading to the limit distribution

$$Q_n = \Delta_n + M_{n-1}\Delta_{n-1}M_{n-1}^T + M_{n-2}^2\Delta_{n-2}(M_{n-2}^2)^T + \cdots .$$

example : noise and a single attractive fixed point

if all eigenvalues of M are strictly contracting, all $|\Lambda_j| < 1$

any initial compact measure converges to the unique invariant Gaussian measure $\rho_0(z)$ whose covariance matrix satisfies

Lyapunov equation: time-invariant measure condition

$$Q = MQM^T + \Delta$$

[A. M. Lyapunov doctoral dissertation 1892]

example : Ornstein-Uhlenbeck process

width of the natural measure concentrated at the attractive deterministic fixed point $z = 0$

$$\rho_0(z) = \frac{1}{\sqrt{2\pi\, Q}} \exp\left(-\frac{z^2}{2\, Q}\right) , \qquad Q = \frac{\Delta}{1 - |\Lambda|^2} ,$$

- is balance between contraction by Λ and noisy smearing by Δ at each time step
- for strongly contracting Λ, the width is due to the noise only
- As $|\Lambda| \to 1$ the width diverges: the trajectories are no longer confined, but diffuse by Brownian motion

example : statistical state dynamics

Brian Farrell

- assume SSD has a single attractive equilibrium
- truncate SSD to the first two cumulants: mean flow, perturbation state covariance C
- closure (drop higher cumulants) by Lyapunov equation

$$\frac{dC}{dt} = A\,C + C\,A^{\dagger} + \epsilon Q\,, \quad A = \text{linearized flow}$$

- works for Jupiter

example : 2D Brusselator limit cycle

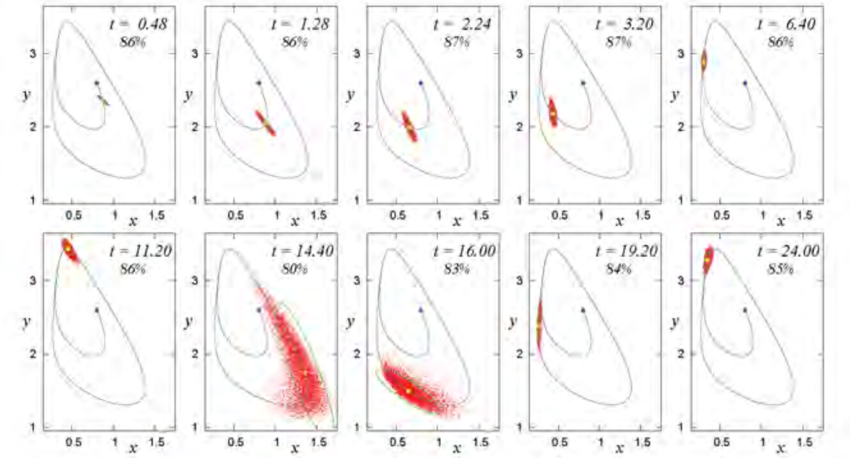


FIG. 2. Time development of distribution for Brusselator. 10 000 samples of Monte Carlo simulations are plotted by the red dots along with the covariance matrix $\hat{M}$ estimated by Eq. (E7); $\hat{M}$'s are represented by the green ellipses given by $\delta \mathbf{x}^T \hat{M}^{-1} \delta \mathbf{x} = 4/\Omega$, where $\delta \mathbf{x}^T \equiv (x - x^*(t), y - y^*(t))$. The percentages of the samples that fall within the ellipses are shown in each panel. The gray curves represent the trajectory by the rate equation starting from the initial point marked by the blue circles. The system parameters are $k_1 = 0.5$, $k_2 = 1.5$, $k_3 = 1.0$, $k_4 = 1.0$, and $\Omega = 10^4$. The initial point is $(x_0^*, y_0^*) = (0.8, 2.6)$.

noisy dynamics of a nonlinear system is fundamentally different from Brownian motion, as the flow ALWAYS induces a local, history dependent effective noise
